## Lab 1: R Basics

Statistical Computing, 36-350

Week of Monday August 26, 2019

Name: Rufus Petrie Andrew ID: Collaborated with:

This lab is to be done in class (completed outside of class if need be). You can collaborate with your classmates, but you must identify their names above, and you must submit **your own** lab as an knitted HTML file on Canvas, by Sunday 11:59pm, this week. Make sure to complete your weekly **check-in** (which can be done by coming to lecture, recitation, lab, or any office hour), as this will count a small number of points towards your lab score.

```
## For reproducibility --- don't change this!
set.seed(09262019)
```

This week's agenda: manipulating data objects; using built-in functions, doing numerical calculations, and basic plots; reinforcing core probabilistic ideas.

#### The binomial distribution

The binomial distribution Bin(m, p) is defined by the number of successes in m independent trials, each have probability p of success. Think of flipping a coin m times, where the coin is weighted to have probability p of landing on heads.

The R function rbinom() generates random variables with a binomial distribution. E.g.,

```
rbinom(n=20, size=10, prob=0.5)
```

produces 20 observations from Bin(10, 0.5).

## Some simple manipulations

• 1a. Generate 300 random values from the Bin(15, 0.5) distribution, and store them in a vector called bin.draws.0.5. Extract and display the first 25 elements. Extract and display all but the first 275 elements.

```
bin.draws.0.5 <- rbinom(n=300, 15, 0.5)
bin.draws.0.5[1:25]

## [1] 10 7 11 7 9 9 6 6 8 6 7 10 10 9 10 8 7 6 8 6 8 5 11 9 9
bin.draws.0.5[276:300]

## [1] 9 8 5 7 8 9 8 8 5 3 6 8 7 11 7 6 12 7 5 9 7 7 4 10 7
```

• 1b. Add the first element of bin.draws.0.5 to the sixth. Compare the second element to the fifth, which is larger? A bit more tricky: print the indices of the elements of bin.draws.0.5 that are equal to 3. How many such elements are there? Theoretically, how many such elements would you expect there to be? Hint: it would be helpful to look at the help file for the rbinom() function.

```
bin.draws.0.5[1] + bin.draws.0.5[6]

## [1] 19
bin.draws.0.5[2] > bin.draws.0.5[5]

## [1] FALSE
which(bin.draws.0.5 == 3)
```

```
## [1] 154 190 285
```

The first plus the sixth element equals 14. The second element is smaller than the fifth. There are 3 elements that equal 3, which is slightly lower than the 4.16 we would expect.

• 1c. Find the mean and standard deviation of bin.draws.0.5. Is the mean close what you'd expect? The standard deviation?

```
mean(bin.draws.0.5)

## [1] 7.57

sd(bin.draws.0.5)
```

```
## [1] 1.89307
```

summary(bin.draws.0.5)

We expect the mean to equal np = 15(0.5) = 7.5 and the standard deviation to equal  $\sqrt{np(1-p)} = \sqrt{15(0.5)(0.5) = 1.93}$ , so these numbers are fairly reasonable.

• 1d. Call summary() on bin.draws.0.5 and describe the result.

```
## Min 1gt On Modion Moon 2nd On More
```

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 2.00 6.00 8.00 7.57 9.00 12.00
```

The median and mean are reasonable (7.5 is the expected value, and 7/8 makes sense for the integer valued median). We did not see too many extreme values in this sample.

• 1e. Find the data type of the elements in bin.draws.0.5 using typeof(). Then convert bin.draws.0.5 to a vector of characters, storing the result as bin.draws.0.5.char, and use typeof() again to verify that you've done the conversion correctly. Call summary() on bin.draws.0.5.char. Is the result formatted differently from what you saw above? Why?

```
typeof(bin.draws.0.5)

## [1] "integer"

bin.draws.0.5.char <- as.character(bin.draws.0.5)
typeof(bin.draws.0.5.char)

## [1] "character"
summary(bin.draws.0.5.char)</pre>
```

```
## Length Class Mode
## 300 character character
```

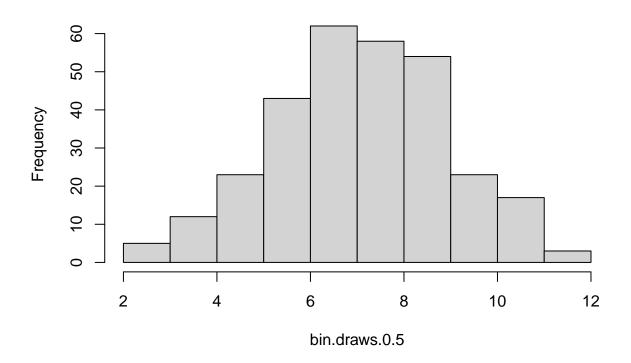

The result is formatted differently because numerical measurements no longer apply to the data.

## Some simple plots

• 2a. The function plot() is a generic function in R for the visual display of data. The function hist() specifically produces a histogram display. Use hist() to produce a histogram of your random draws from the binomial distribution, stored in bin.draws.0.5.

hist(bin.draws.0.5)

# Histogram of bin.draws.0.5

• **2b.** Call tabulate() on bin.draws.0.5. What is being shown? Does it roughly match the histogram you produced in the last question?

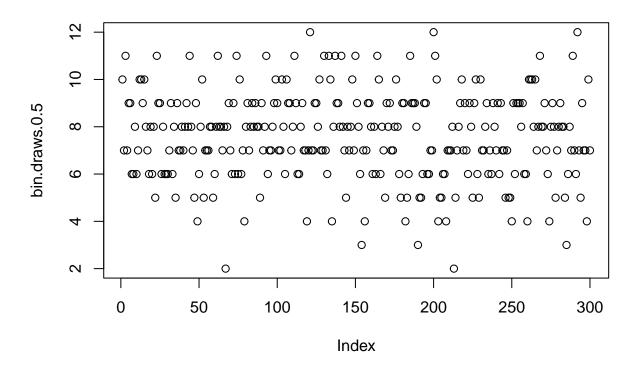

tabulate(bin.draws.0.5)

## [1] 0 2 3 12 23 43 62 58 54 23 17 3

This shows the amounts of each observation in bin.draws.0.5. This roughly matches what we saw in the histogram.

• 2c. Call plot() on bin.draws.0.5 to display your random values from the binomial distribution. Can you interpret what the plot() function is doing here?

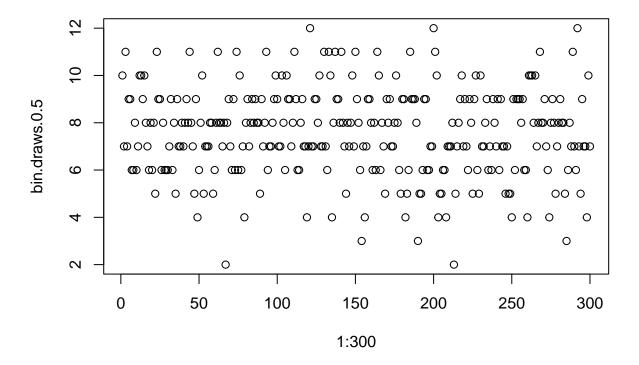

plot(bin.draws.0.5)

This function plots the result of each binomial trial in order from 1 to 300.

• 2d. Call plot() with two arguments, the first being 1:300, and the second being bin.draws.0.5. This creates a scatterplot of bin.draws.0.5 (on the y-axis) versus the indices 1 through 300 (on the x-axis). Does this match your plot from the last question?

plot(1:300, bin.draws.0.5)

This matches the results from the previous plot.

## More binomials, more plots

• 3a. Generate 300 binomials again, composed of 15 trials each, but change the probability of success to: 0.2, 0.3, 0.4, 0.6, 0.7, and 0.8, storing the results in vectors called bin.draws.0.2, bin.draws.0.3, bin.draws.0.4., bin.draws.0.6, bin.draws.0.7 and bin.draws.0.8. For each, compute the mean and standard deviation.

```
bin.draws.0.2 <- rbinom(n=300, 15, 0.2)
mean(bin.draws.0.2)
## [1] 2.963333
sd(bin.draws.0.2)
## [1] 1.517563
bin.draws.0.3 <- rbinom(n=300, 15, 0.3)
mean(bin.draws.0.3)
## [1] 4.373333
sd(bin.draws.0.3)</pre>
## [1] 1.707926
```

```
bin.draws.0.4 <- rbinom(n=300, 15, 0.4)
mean(bin.draws.0.4)
## [1] 5.933333
sd(bin.draws.0.4)
## [1] 1.995536
bin.draws.0.6 <- rbinom(n=300, 15, 0.6)
mean(bin.draws.0.6)
## [1] 9.043333
sd(bin.draws.0.6)
## [1] 1.758341
bin.draws.0.7 <- rbinom(n=300, 15, 0.7)
mean(bin.draws.0.7)
## [1] 10.56
sd(bin.draws.0.7)
## [1] 1.71743
bin.draws.0.8 <- rbinom(n=300, 15, 0.8)
mean(bin.draws.0.8)
## [1] 12.05
sd(bin.draws.0.8)
```

## [1] 1.499442

• **3b.** We'd like to compare the properties of our vectors. Create a vector of length 7, whose entries are the means of the 7 vectors we've created, in order according to the success probabilities of their underlying binomial distributions (0.2 through 0.8).

```
means <- c(mean(bin.draws.0.2), mean(bin.draws.0.3), mean(bin.draws.0.4), mean(bin.draws.0.5), mean(bin.draws.0.5), sd(bin.draws.0.2), sd(bin.draws.0.3), sd(bin.draws.0.4), sd(bin.draws.0.5), sd(bin.draws.0.6),
```

- 3c. Using the vectors from the last part, create the following scatterplots. Explain in words, for each, what's going on
  - The 7 means versus the 7 probabilities used to generate the draws.
  - The standard deviations versus the probabilities.
  - The standard deviations versus the means.

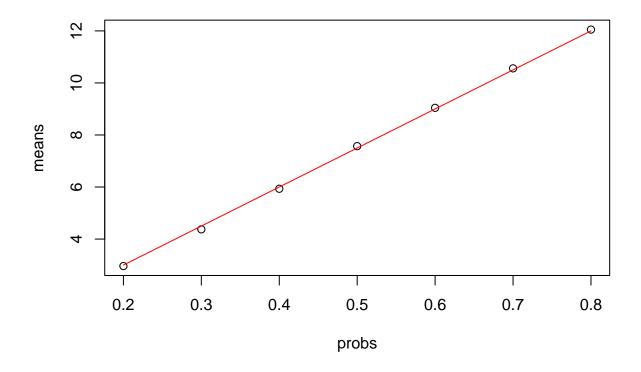

**Challenge**: for each plot, add a curve that corresponds to the relationships you'd expect to see in the theoretical population (i.e., with an infinite amount of draws, rather than just 300 draws).

```
probs <- c()
for(i in 2:8){
   probs <- c(probs, i/10)
}

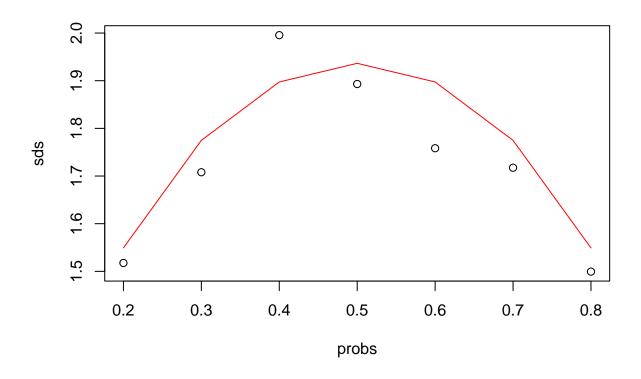

mean_line <- probs * 15

sd_line <- c()
for(i in 2:8){
   sd_line <- c(sd_line, sqrt(15 * (i/10) * (1-i/10)))
}</pre>
```

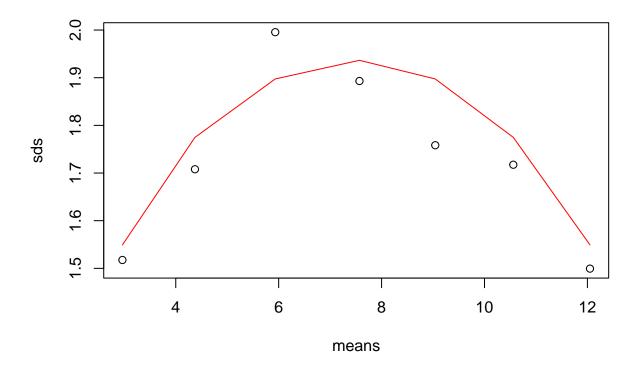

```
plot(probs, means)
lines(probs, mean_line, col="red")
```

plot(probs, sds)
lines(probs, sd\_line, col="red")

plot(means, sds)
lines(means, sd\_line, col="red")

As the probability increases, the mean linearly increases. As the probability increases, the standard deviation increases and peaks at around 0.5, then decreases. The standard deviation has the same relationship with means as it has with probabilities.

# Working with matrices

• 4a. Create a matrix of dimension 300 x 7, called bin.matrix, whose columns contain the 7 vectors we've created, in order of the success probabilities of their underlying binomial distributions (0.2 through 0.8). Hint: use cbind().

```
bin.matrix <- matrix(bin.draws.0.2)
bin.matrix <- cbind(bin.matrix, bin.draws.0.3)
bin.matrix <- cbind(bin.matrix, bin.draws.0.4)
bin.matrix <- cbind(bin.matrix, bin.draws.0.5)
bin.matrix <- cbind(bin.matrix, bin.draws.0.6)
bin.matrix <- cbind(bin.matrix, bin.draws.0.7)
bin.matrix <- cbind(bin.matrix, bin.draws.0.8)
colnames(bin.matrix) <- probs</pre>
```

• 4b. Print the first five rows of bin.matrix. Print the element in the 66th row and 5th column. Compute the largest element in first column. Compute the largest element in all but the first column.

```
## 0.2 0.3 0.4 0.5 0.6 0.7 0.8
## [1,] 2 6 5 10 6 10 11
```

bin.matrix[1:5,]

```
## [2,]
           3
                    5
                         7
                            12
                                     14
                        11
   [3.]
           0
                7
                    6
                             7
                                     12
                                  9
## [4,]
           3
                5
                    6
                         7
                              9
                                 11
                                     12
           2
                2
                    9
                         9
                              8
                                     10
## [5,]
                                  9
bin.matrix[66,5]
## 0.6
##
max(bin.matrix[,-1])
```

## [1] 15

• 4c. Calculate the column means of bin.matrix by using just a single function call.

```
colMeans(bin.matrix)
```

```
## 0.2 0.3 0.4 0.5 0.6 0.7 0.8
## 2.963333 4.373333 5.933333 7.570000 9.043333 10.560000 12.050000
```

• 4d. Compare the means you computed in the last question to those you computed in Q3b, in two ways. First, using ==, and second, using identical(). What do the two ways report? Are the results compatible? Explain.

```
means == colMeans(bin.matrix)

## 0.2 0.3 0.4 0.5 0.6 0.7 0.8

## TRUE TRUE TRUE TRUE TRUE TRUE
identical(means, colMeans(bin.matrix))
```

## [1] FALSE

• **4e.** Take the transpose of bin.matrix and then take row means. Are these the same as what you just computed? Should they be?

```
rowMeans(t(bin.matrix))

## 0.2 0.3 0.4 0.5 0.6 0.7 0.8

## 2.963333 4.373333 5.933333 7.570000 9.043333 10.560000 12.050000
```

They are the same and should be. Transposing turns the columns into the rows, so taking the rowmean will yield the old column means.

# Warm up is over, let's go big

• 5a. R's capacity for data storage and computation is very large compared to what was available 10 years ago. Generate 3 million numbers from  $Bin(1 \times 10^6, 0.5)$  distribution and store them in a vector called big.bin.draws. Calculate the mean and standard deviation of this vector.

```
big.bin.draws <- rbinom(3*10^6, 10^6, 0.5)
mean(big.bin.draws)

## [1] 499999.8
sd(big.bin.draws)

## [1] 500.0116</pre>
```

• **5b.** Create a new vector, called big.bin.draws.standardized, which is given by taking big.bin.draws, subtracting off its mean, and then dividing by its standard deviation. Calculate the mean and standard deviation of big.bin.draws.standardized. (These should be 0 and 1, respectively, or very, very close to it; if not, you've made a mistake somewhere).

big.bin.draws.standardized <- (big.bin.draws - mean(big.bin.draws))/sd(big.bin.draws)
mean(big.bin.draws.standardized)</pre>

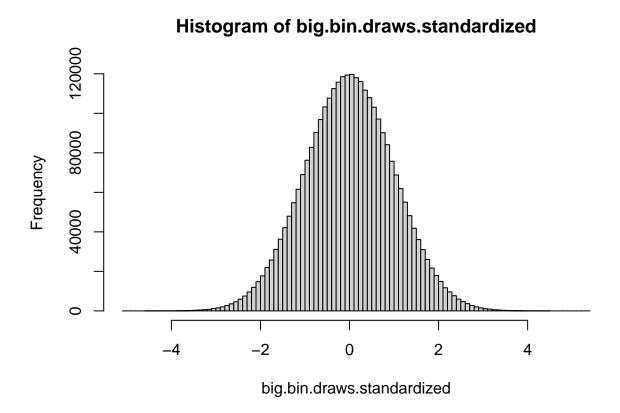

## [1] -4.236492e-14

sd(big.bin.draws.standardized)

#### ## [1] 1

• 5c. Plot a histogram of big.bin.draws.standardized. To increase the number of histogram bars, set the breaks argument in the hist() function (e.g., set breaks=100). What does the shape of this histogram appear to be? Is this surprising? What could explain this phenomenon? Hint: rhymes with "Mental Gimmick Serum"...

hist(big.bin.draws.standardized, breaks=100)

The shape of this histogram appears to be a bell curve. This isn't surprising because repeated samples from a distribution are normally distributed because of the Central Limit Theorem.

• **5d.** Calculate the proportion of times that an element of big.bin.draws.standardized exceeds 1.644854. Is this close to 0.05?

sum((big.bin.draws.standardized>1.644854))/(3\*10^6)

## [1] 0.049991

This is reasonably close to 0.05.

• 5e. Either by simulation, or via a built-in R function, compute the probability that a standard normal random variable exceeds 1.644854. Is this close to 0.05? Hint: for either approach, it would be helpful to look at the help file for the rnorm() function.

```
rn <- rnorm(3*10^6)
sum(rn>1.644854)/(3*10^6)
## [1] 0.05006333
```

This is pretty close to 0.05.

## Now let's go really big

• 6a. Let's push R's computational engine a little harder. Design an expression to generate 100 million numbers from Bin(10 × 10<sup>6</sup>, 50 × 10<sup>-8</sup>), to be saved in a vector called huge.bin.draws, but do not evaluate this command yet. Then ask your lab partner to name three of Justin Bieber's songs and simultaneously evaluate your R command that defines huge.bin.draws. Which finished first, R or your partner? (Note: your partner cannot really win this game. Even if he/she finishes first, he/she still loses.)

```
t1 <- Sys.time()
huge.bin.draws <- rbinom(100*10^6, 10*10^6, 50*10^-8)
t2 <- Sys.time()
t2-t1</pre>
```

## Time difference of 14.89116 secs

R finished first.

• 6b. Calculate the mean and standard deviation of huge.bin.draws. Are they close to what you'd expect? (They should be very close.) Did did longer to compute these, or to generate huge.bin.draws in the first place?

```
t1 <- Sys.time()
mean(huge.bin.draws)

## [1] 4.999943

sd(huge.bin.draws)

## [1] 2.235891

t2 <- Sys.time()
t2-t1</pre>
```

## Time difference of 1.330052 secs

The outputs are very close to the expected results of 5 and 2.23. It took longer to generate huge bin.draws.

• 6c. Calculate the median of huge.bin.draws. Did this median calculation take longer than the calculating the mean? Is this surprising?

```
t1 <- Sys.time()
median(huge.bin.draws)

## [1] 5

t2 <- Sys.time()
t2-t1</pre>
```

#### ## Time difference of 2.498747 secs

The median calculation took longer than calculating the mean. This isn't surprising because the median is calculated in nlogn time whereas the mean is calculated in linear time.

• 6d. Calculate the exponential of the median of the logs of huge.bin.draws, in one line of code. Did this take longer than the median calculation applied to huge.bin.draws directly? Is this surprising?

```
t1 <- Sys.time()
exp(median(log(huge.bin.draws)))
## [1] 5
t2 <- Sys.time()
t2-t1</pre>
```

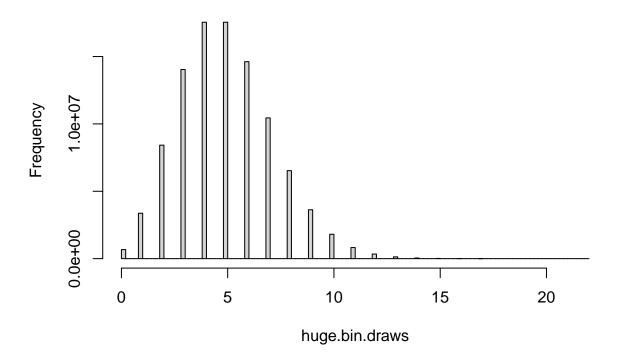

#### ## Time difference of 8.344442 secs

This took longer than the direct median calculation. This isn't surprising because R has to perform two more actions on each element of the list.

• 6e. Plot a histogram of of huge.bin.draws, again with a large setting of the breaks argument (e.g., breaks=100). Describe what you see; is this different from before, when we had 3 million draws? Challenge: Is this surprising? What distribution is this?

hist(huge.bin.draws, breaks=100)

# Histogram of huge.bin.draws

This is different from above when we had fewer draws. This change isn't necessarily exciting because the value of the distribution stops in one direction at zero, but can expend much longer on the other direction as we add additional trials.

## Going big with lists

• 7a. Convert big.bin.draws into a list using as.list() and save the result as big.bin.draws.list. Check that you indeed have a list by calling class() on the result. Check also that your list has the right length, and that its 1159th element is equal to that of big.bin.draws.

```
big.bin.draws.list <- as.list(big.bin.draws)
class(big.bin.draws.list)

## [1] "list"
length(big.bin.draws.list)

## [1] 3000000
big.bin.draws.list[1159] == big.bin.draws[1159]</pre>
```

## [1] TRUE

• 7b. Run the code below, to standardize the binomial draws in the list big.bin.draws.list. Note that lapply() applies the function supplied in the second argument to every element of the list supplied in the first argument, and then returns a list of the function outputs. (We'll learn much more about the apply() family of functions later in the course.) Did this lapply() command take longer to evaluate than the code you wrote in Q5b? (It should have; otherwise your previous code could have been improved, so go back and improve it.) Why do you think this is the case?

```
big.bin.draws.mean = mean(big.bin.draws)
big.bin.draws.sd = sd(big.bin.draws)
standardize = function(x) {
  return((x - big.bin.draws.mean) / big.bin.draws.sd)
}
big.bin.draws.list.standardized.slow = lapply(big.bin.draws.list, standardize)
```

CBA'd going back and setting up timer, but this one obviously applies a function to each element of the list instead of doing element-wise calculations on the vectors, so the computer uses significantly more overhead to complete this calculation.

• 7c. Run the code below, which again standardizes the binomial draws in the list big.bin.draws.list, using lapply(). Why is it so much slower than the code in the last question? Think about what is happening each time the function is called.

```
big.bin.draws.mean = mean(big.bin.draws)
big.bin.draws.sd = sd(big.bin.draws)
standardize.slow = function(x) {
   return((x - mean(big.bin.draws)) / sd(big.bin.draws))
}
big.bin.draws.list.standardized.slow = lapply(big.bin.draws.list, standardize.slow)
```

This one is even worse because each time the function is called, it has to recalculate the mean and standard deviation of big.bin.draws instead of calculating them once and saving them as constants.

• 7d. Lastly, let's look at memory useage. The command object.size(x) returns the number of bytes used to store the object x in your current R session. Find the number of bytes used to store big.bin.draws and big.bin.draws.list. How many megabytes (MB) is this, for each object? Which object requires more memory, and why do you think this is the case? Remind yourself: why are lists special compared to vectors, and is this property important for the current purpose (storing the binomial draws)?

### object.size(big.bin.draws)

### ## 12000048 bytes

object.size(big.bin.draws.list)

### ## 192000048 bytes

The vector requires 12 MB, whereas the list requires 192 MB. The list requires more memory because it needs to allow for each element to be a different datatype. This capability isn't required for this problem because we only store integer values in our data structure. so we should obviously use vectors in this scenario.
